Mobile-First Design Implementation

I followed a mobile-first design strategy by writing my base CSS for small screens first and then building additional behavior through media queries and responsive layouts. Designing for mobile first ensures that the most important content remains readable and functional on smaller devices, which are often the primary way users access websites.

I structured the layout so that elements stack vertically and are easy to scroll through. Content sections include consistent spacing through margins and padding so that the page remains readable without feeling crowded. Images are responsive and scale relative to the screen width, preventing them from becoming too large on smaller displays.

I also implemented collapsible sections using expandable summary elements. These sections allow users to tap to reveal additional race information instead of displaying everything at once. This design keeps the mobile interface clean and easy to navigate while still providing detailed information when users want it.

The podium ranking section was designed to adapt to mobile screens by displaying content in a single column layout. This ensures that the information remains readable without requiring horizontal scrolling.

CSS Quality and Organization

My CSS includes comments explaining design decisions and where inspiration came from. I organized my styles using reusable class selectors so that I could avoid repeating the same styling rules in multiple places.

For example, I created reusable classes for layout structures such as profile grids, meet cards, and podium sections. These classes help maintain consistency across the site and make the CSS easier to maintain. I also used consistent spacing, typography, and color schemes to ensure that the visual design remains cohesive.

Grid was used to organize larger layout sections, such as the podium ranking display, while Flexbox was used within cards and containers to align and distribute content evenly.

Innovative Styling Features

In addition, I incorporated some styling techniques that were not directly shown in class. For example, I implemented animated hover effects in the navigation bar, custom transitions for interactive elements, and dynamic layout adjustments using CSS Grid and Flexbox together.

More specifically, I designed the navigation bar with animated hover effects that create a sliding background animation when users interact with navigation links. This adds visual feedback and improves the overall interface.

I also used alternating visual elements such as borders and background colors to distinguish podium rankings for gold, silver, and bronze athletes. This makes the ranking information immediately recognizable to users.

Animations and Interactive Elements

I incorporated animations into the site to enhance the user experience while keeping them subtle and performance-friendly. My goal was to make the interface feel dynamic without overwhelming the user.

For example, images slightly enlarge when users interact with them, creating a tactile and responsive effect that works well on touch screens. I also implemented animated transitions for the podium ranking cards. These cards fade into view and slide upward as the page loads. Each ranking card appears with a slight delay, which visually reinforces the order of the rankings.

Navigation items also include animated hover effects. When users hover over a navigation button, the background color slides across the button while the text color changes. This animation provides clear feedback that the element is interactive.

Accessibility Features

One accessibility feature I included is a skip navigation link. This link allows keyboard users to jump directly to the main content without navigating through every item in the navigation menu. The skip link becomes visible when it receives keyboard focus.

I also added visible focus styles to highlight interactive elements when users navigate the page using a keyboard. This helps users understand where they are on the page and improves navigation for keyboard and screen reader users.

Another important accessibility feature is support for reduced motion preferences. I implemented the prefers-reduced-motion media query so that users who prefer reduced motion will not experience animations or transitions that could cause discomfort.

Accessibility Validation

I used the WAVE Web Accessibility Evaluation Tool to identify potential accessibility issues such as missing alternative text, structural errors, or color contrast problems. I also used the aXe accessibility testing tool to verify that the site follows accessibility best practices.
